1 INTRODUCTION

- 1.1 Entran Ltd has been commissioned to undertake a noise assessment for a proposed residential development at 52 New Street, Ash, Nr Wingham.
- 1.2 The assessment has been prepared to support a planning application for the Proposed Development to be submitted to Dover District Council. This assessment has been undertaken to consider the noise levels at the proposed residential development. The assessment considers the existing ambient noise and the suitability of the site for residential use.
- 1.3 The potential noise impacts are assessed in accordance with the most relevant national and local standards and guidelines.
- 1.4 The noise levels are assessed using criteria provided within BS 8233:2014 and the WHO Guidelines. This report is necessarily technical in nature and contains terminology relating to acoustics and noise. Therefore, a glossary together with a brief introduction to the subject of noise has been provided in Appendix A.

2 SITE DESCRIPTION

- 2.1 The Proposed Development scheme comprises “*outline planning permission with all matters reserved (except for access) for the demolition of existing buildings, including 51-53 Sandwich Road, and the erection of up to 52 new homes, including affordable, access from New Street and Sandwich Road, together with associated parking, open space, landscaping, drainage and associated infrastructure*”.
- 2.2 The site is situated to the north of New Street. Sandwich Road runs adjacent to the northern boundary of the site. The surrounding area comprises largely open grassland and residential dwellings. A storage facility and music school are situated to the north east of the site at 63-65 Sandwich Road and are understood to generate occasional vehicle movements.
- 2.3 The existing noise climate within the vicinity of the Proposed Development is dominated by local road traffic on New Street and Sandwich Road and distant road traffic on the surrounding road network.
- 2.4 The Proposed Development location and boundary are indicated in Figure 1.

Figure 1 – Site Location

3 ASSESSMENT METHODOLOGY

National Policy

National Planning Policy Framework (NPPF) (July 2021)

3.1 The National Planning Policy Framework (NPPF) sets out the Government's economic, environmental and social planning policies for England. It attempts to summarise in a single document all previous national planning policy advice. Taken together, these policies articulate the Government's vision of sustainable development, which should be interpreted and applied locally to meet local aspirations.

3.2 Under Section 15; Conserving and enhancing the natural environment, the following is stated in paragraph 174:

"Planning policies and decisions should contribute to and enhance the natural and local environment by: ...

preventing new and existing development from contributing to, being put at unacceptable risk from, or being adversely affected by, unacceptable levels of soil, air, water or noise pollution or land instability..."

3.3 The NPPF goes on to state in paragraph 185 that:

"Planning policies and decisions should also ensure that new development is appropriate for its location taking into account the likely effects (including cumulative effects) of pollution on health, living conditions and the natural environment, as well as potential sensitivity of the site or the wider area to impacts that could arise from the development. In doing so they should:

mitigate and reduce to a minimum potential adverse impacts resulting from noise from new development – and avoid noise giving rise to significant adverse impacts on health and the quality of life;

identify and protect tranquil areas which have remained relatively undisturbed by noise and are prized for their recreational and amenity value for this reason"

Noise Policy Statement for England NPSE (March 2010)

3.4 The Government is committed to sustainable development and the Department for Environment Food and Rural Affairs (Defra) plays an important role in this by working to secure a healthy environment in which current and future generations can prosper. One aspect of meeting these objectives is the need to manage noise for which Defra has the overall responsibility in England.

3.5 In March 2010, the Noise Policy Statement for England (NPSE) set out the long-term vision of Government noise policy as to:

'Promote good health and a good quality of life through the effective management of noise within the context of Government policy on sustainable development.'

3.6 The long-term vision is supported by the following aims:

'Through the effective management and control of environmental, neighbour and neighbourhood noise within the context of Government policy on sustainable development:

- *Avoid significant adverse impacts on health and quality of life;*
- *Mitigate and minimise adverse impacts on health and quality of life: and,*
- *Where possible, contribute to the improvement of health and quality of life.'*

3.7 The explanatory note to the policy statement emphasises that sustainable development is a core principle underpinning all government policy. In this respect, there is a need to integrate consideration of the economic and social benefit of the activity under examination with proper consideration of the adverse environmental effects.

3.8 To achieve these objectives the NPSE sets out three noise conditions to be determined by the assessor:

NOEL - No Observed Effect Level

3.9 This is the level below which no effect can be detected. In simple terms, below this level there is no detectable effect on health and quality of life due to the noise.

LOAEL - Lowest Observed Adverse Effect Level

3.10 This is the level above which adverse effects on health and quality of life can be detected.

SOAEL - Significant Observed Adverse Effect Level

- 3.11 This is the level above which significant adverse effects on health and quality of life occur.
- 3.12 The NPSE considers that noise levels above the SOAEL would be seen to have, by definition, significant adverse effects and would be considered unacceptable.
- 3.13 Where the assessed noise levels fall between the LOAEL and the SOAEL noise levels, the NPSE requires that:

'All reasonable steps should be taken to mitigate and minimise adverse effects on health and quality of life while also taking into account the guiding principles of sustainable development.... This does not mean that such adverse effects cannot occur.'

- 3.14 No objective values are offered within the NPSE, as the document does indicate that each site should be considered on its own merits. Consequently, consideration of the observed effects is made through an assessment methodology as detailed below.

British Standard BS 8233:2014 Guidance on Sound Insulation and Noise Reduction for Buildings (2014)

- 3.15 The scope of BS 8233 is the provision of recommendations for the control of noise in and around buildings. It suggests appropriate criteria and limits for different situations, which are primarily intended to guide the design of new or refurbished buildings undergoing a change of use rather than to assess the effect of changes in the external noise climate.
- 3.16 This Standard suggests suitable internal noise levels within different types of buildings, including residential dwellings. It suggests that an internal noise level of 30 dB $L_{Aeq, T}$ within bedrooms is a 'desirable' standard. For living areas during the daytime, the standard recommends 35 dB $L_{Aeq, T}$ as a desirable standard for resting.
- 3.17 Whilst BS 8233 recognises that a guideline value may be set in terms of SEL or L_{AFmax} for the assessment of regular individual noise events that can cause sleep disturbance during the night-time, a specific criterion is not stipulated. Accordingly, reference has been made in this assessment to the World Health Organisation (WHO) 1999: *Guidelines for Community Noise*.

3.18 The Standard also states that “*where development is considered necessary or desirable, despite external noise levels above WHO guidelines, the internal target levels may be relaxed by up to 5 dB and reasonable internal conditions still achieved.*”

The Institute of Environmental Management & Assessment (IEMA) Guidelines for Environmental Noise Impact Assessment (2014)

3.19 The Institute of Environmental Management and Assessment (IEMA) have recently published the ‘*Guidelines for Environmental Noise Impact Assessment*’. The guidelines are applicable to noise impact assessment for any scale of development proposal, including core principles to achieve effectively integration with the EIA, and provide advice on the issues that need to be considered in a noise impact assessment and whether the appropriate conclusions are being reached. The factors include:

- The appropriateness of the noise parameters used for the situation;
- The reference time period used in making the assessment;
- The level, character and frequency content of the noise sources under investigation; and,
- How the predicted noise levels relate to relevant Standards and guidelines.

3.20 The guidelines also recommend that the assessor should determine the degree of impact based on evidence derived from the assessment.

The Professional Practice Guidance on Planning and Noise (2017)

3.21 The ‘*Professional Practice Guidance on Planning and Noise*’ (ProPG) has been produced by a Working Group consisting of representatives of the Association of Noise Consultants (ANC), Institute of Acoustics (IOA) and Chartered Institute of Environmental Health (CIEH) to provide acoustical practitioners with guidance on the management of noise within the planning system in England.

3.22 The reparation of the ProPG acknowledges and reflects the Government’s overarching NPSE, the NPPF and Planning Practice Guidance (including PPG-Noise), as well as other authoritative sources of guidance. It provides advice for Local Planning Authorities (LPAs) and developers, and their respective professional advisers which complements Government planning and noise policy and guidance and, in particular, aims to:

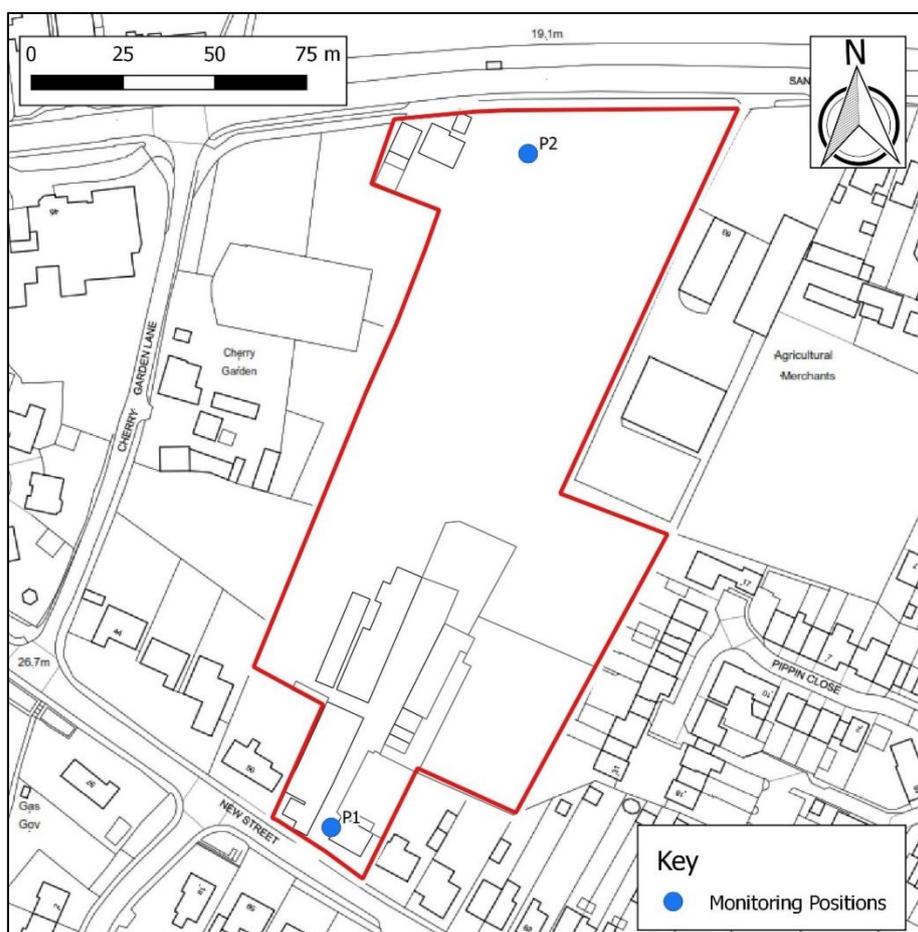

-
- advocate full consideration of the acoustic environment from the earliest possible stage of the development control process;
 - encourage the process of good acoustic design in and around new residential developments;
 - outline what should be taken into account in deciding planning applications for new noise-sensitive developments;
 - promote appropriate noise exposure standards; and,
 - assist the delivery of sustainable development.

4 ENVIRONMENTAL NOISE MEASUREMENTS

- 4.1 Noise conditions in the vicinity of the Proposed Development have been determined by an environmental noise survey conducted between 1st and 3rd August 2022.
- 4.2 No on-site movements were observed at the nearby storage facility and observations indicate that general activity on the site is minimal. The music school building is sound proofed and no noise was observed from the music school building. Any noise emanating from the site forms part of the ambient environment and not considered likely to give rise to significant impacts.
- 4.3 The monitors were placed at positions close to Sandwich Road and New Street in order to obtain measurements of passing traffic. The monitor at P1 was situated approximately 2 m above local ground and P2 was situated approximately 1.8m above local ground level. The monitoring positions are indicated in Figure 2.

Figure 2 – Unattended Monitoring Locations

4.4 A summary of the unattended survey is provided in Table 1 and graphical representation of the unattended results is presented in Figures B1 and B2 of Appendix B.

Table 1: Summary of Existing Noise Data

| Position | Measured Free-Field Sound Pressure Level, dB re. 2×10^{-5} Pa. | | | | | |
|----------|---|-------------|-------------|----------------------------|-------------|-------------|
| | Day Time (07:00 - 23:00) | | | Night-time (23:00 - 07:00) | | |
| | $L_{Amax,F}$ | $L_{Aeq,T}$ | $L_{A90,T}$ | $L_{Amax,F}$ | $L_{Aeq,T}$ | $L_{A90,T}$ |
| P1 | 89.7 | 54.6 | 35.2 | 80.4 | 44.3 | 25.6 |
| P2 | 80.9 | 49.4 | 39.9 | 77.9 | 43.7 | 28.3 |

Maximum levels represent the highest $L_{Amax,F}$ sound level during the given period.
The period $L_{Aeq,T}$ is obtained from the logarithmic average of measured sound levels.
The period $L_{A90,T}$ is obtained from the average of the measured sound levels.
Data removed between 5th and 7th November due to bonfire night celebrations

- 4.5 The unattended noise monitoring was undertaken to validate a computer noise model and to inform assessment in accordance with BS 8233; to determine the level of glazing/ventilation required to reduce the likelihood of adverse effects relating to the Proposed Development.
- 4.6 All noise measurements were undertaken by competent individuals with experience in environmental noise monitoring. Measurements were obtained in accordance with the principles of BS 7445: 2003: '*Description and measurement of environmental noise*'.
- 4.7 All acoustic measurement equipment used during the noise surveys conformed to Type 1 specification of British Standard 61672: 2003: '*Electroacoustics. Sound level meters. Part 1 Specifications*'. The noise measurement equipment used during the survey was calibrated at the start and end of the measurement period. There was no significant drift in calibration measurements observed during the survey period.
- 4.8 Each microphone was fitted with a protective windshield and the sound level meters were situated in a weatherproof case. Consideration of weather conditions and stability of the unattended data indicates that the weather conditions during the survey did not significantly affect the survey.

5 NOISE ASSESSMENT

Ambient Noise Levels

- 5.1 Noise emission levels affecting the Proposed Development have been calculated using predictive computer noise modelling. The noise modelling software (Cadna-A) uses algorithms based on ISO 9613 'Attenuation of sound during outdoor propagation' to predict noise levels generated at receiver locations by noise sources.
- 5.2 The results of the ambient noise survey have been used to calculate the noise emissions from nearby road sources. Noise levels have been presented as contours, calculated across the site at a height of 1.5m and 4m above ground level for day and night-time periods, respectively.
- 5.3 The calculated daytime and night-time noise contours are presented in Figures B4 and B5 of Appendix B.
- 5.4 The typical façade reduction afforded by insulated double glazing and attenuated trickle ventilation is given within BS 8233 as 33 dB. For partially open windows the reduction is given as 15 dB.
- 5.5 With consideration to these reductions, noise levels are calculated to achieve the BS 8233 criteria with closed windows at all areas within the Proposed Development. Areas not overlooking road sources are calculated to achieve the BS 8233 criteria with windows partially open.
- 5.6 The reductions as provided within BS 8233 indicate that typical insulated double glazing and attenuated trickle ventilation would be sufficient to mitigate noise levels within all residential dwellings at the Proposed Development.
- 5.1 Daytime noise levels across the Proposed Development are calculated to fall below the BS 8233 upper guideline noise level for external amenity. Accordingly, no requirement for mitigation is identified.
- 5.2 The WHO Guidelines states that indoor noise levels should not exceed approximately 45 dB L_{Amax} more than 10-15 times a night to ensure there are no negative health effects related to sleep disturbance.

5.3 Considering the façade sound reduction from typical design, as used in the BS 8233 assessment, maximum night time noise levels at both monitoring locations with windows closed and are unlikely to exceed the WHO criteria.

6 MITIGATION

- 6.1 Measured ambient noise levels are considered to satisfy the criteria provided within BS 8233 with the incorporation of typical insulated double glazing and attenuated trickle ventilation. No further specific consideration of mitigation is identified as required.
- 6.2 Assessment of maximum $L_{Amax,F}$ noise levels indicates the development will achieve the WHO criteria with windows closed, with the guideline noise level being exceeded for no more than three times per night.
- 6.3 Windows are not required to be sealed and may remain openable to be used at the discretion of occupants.
- 6.4 Notwithstanding the above, it would be prudent to ensure that any glazing and ventilation is specified to achieve at least 30 dB R_W+C_{tr} at properties overlooking roads. This value is typically afforded by insulated double glazing. Ventilation should be specified to achieve a reduction 30 dB and include correction for the C_{tr} urban road traffic spectrum. Any passive ventilation should achieve this value when open, to allow ventilation to the dwelling. Additionally, the glazing and ventilation installation must maintain the integrity of the façade with regard to noise insulation.
- 6.5 The adjacent storage facility and music rooms are not considered to give rise to significant levels of noise. Calculated and measured ambient noise levels are sufficiently low that any noise emissions from the site would not be likely to give rise to significant ambient noise levels. Whilst no further assessment has been identified as required, the applicant has advised that solid close boarded fencing at least 2m in height will be installed at the boundaries with the site in order to further ensure the likelihood of effects remain low.
- 6.6 In order to provide adequate acoustic screening any barrier material should have a mass per unit of surface area in excess of 12 Kg/m² and be of a continuous/close-boarded construction with a minimum thickness of 15 mm. The fence should be suitably treated to prevent warping and rot due to weathering.

7 CONCLUSIONS

- 7.1 An assessment of the potential noise impacts attributable to the existing ambient environment has been undertaken for the Proposed Development at 52 New Street, Ash, Nr Wingham.
- 7.2 The assessment has been based on a computer noise model, informed and validated using ambient noise measurements undertaken during an unattended noise. Ambient noise levels are calculated to achieve the criteria provided within BS 8233:2014 and the WHO Guidelines for Community Noise.
- 7.3 Typical insulated double glazing and attenuated trickle ventilation is calculated to be sufficient across the site, although it would be prudent to ensure items are selected to achieve a reduction of at least 30 dB $R_{W+C_{tr}}$ at dwellings overlooking roads. However, windows are not required to be sealed and may remain openable for rapid or purge ventilation or to be opened at the occupant's discretion.
- 7.4 External amenity noise levels are calculated to fall below the guideline noise level for external amenity and therefore no consideration of mitigation is required.

APPENDIX A – INTRODUCTION TO NOISE

In order to assist the understanding of acoustic terminology and the relative change in noise, the following background information is provided.

The human ear can detect a very wide range of pressure fluctuations, which are perceived as sound. In order to express these fluctuations in a manageable way, a logarithmic scale called the decibel, or dB scale is used. The decibel scale typically ranges from 0 dB (the threshold of hearing) to over 120 dB.

The ear is less sensitive to some frequencies than to others. The A-weighting scale is used to approximate the frequency response of the ear. Levels weighted using this scale are commonly identified by the notation dB(A).

A noise impact on a community is deemed to occur when a new noise is introduced that is out of character with the area, or when a significant increase above the pre-existing ambient noise level occurs. For levels of noise that vary with time, it is necessary to employ a statistical index that allows for this variation. These statistical indices are expressed as the sound level that is exceeded for a percentage of the time period of interest.

In the UK, traffic noise is measured as the L_{A10} , the noise level exceeded for 10% of the measurement period. The L_{A90} is the level exceeded for 90% of the time and has been adopted to represent the background noise level in the absence of discrete events. An alternative way of assessing the time varying noise levels is to use the equivalent continuous sound level, L_{Aeq} . This is a notional steady level that would, over a given period of time, deliver the same sound energy as the actual fluctuating sound.

To put these quantities into context, where a receiver is predominantly affected by continuous flows of road traffic, a doubling or halving of the flows would result in a just perceptible change of 3dB, while an increase of more than 25%, or a decrease of more than 20%, in traffic flows represent changes of 1dB in traffic noise levels (assuming no alteration in the mix of traffic or flow speeds).

Note that the time constant and the period of the noise measurement should be specified. For example, BS 4142 specifies background noise measurement periods of 1 hour during the day and 5 minutes during the night. The noise levels are commonly symbolised as $L_{A90(1hour)}$ and $L_{A90(5mins)}$. The noise measurement should be recorded using a 'FAST' time response equivalent to 0.125 ms.

Table A1: Glossary of Terms

| Term | Definition |
|----------------------|--|
| Decibel (dB) | A scale for comparing the ratios of two quantities, including sound pressure and sound power. The difference in level between two sounds s_1 and s_2 is given by $20 \log_{10} (s_1/s_2)$. The decibel can also be used to measure absolute quantities by specifying a reference value that fixes one point on the scale. For sound pressure, the reference value is $20\mu\text{Pa}$. |
| A-weighting, dB(A) | The unit of sound level, weighted according to the A-scale, which takes into account the increased sensitivity of the human ear at some frequencies. |
| Noise Level Indices | Noise levels usually fluctuate over time, so it is often necessary to consider an average or statistical noise level. This can be done in several ways, so a number of different noise indices have been defined, according to how the averaging or statistics are carried out. |
| $L_{eq,T}$ | A noise level index called the equivalent continuous noise level over the time period T. This is the level of a notional steady sound that would contain the same amount of sound energy as the actual, possibly fluctuating, sound that was recorded. |
| $L_{max,F}$ | A noise level index defined as the maximum noise level during the period T. L_{max} is sometimes used for the assessment of occasional loud noises, which may have little effect on the overall L_{eq} noise level but will still affect the noise environment. Unless described otherwise, it is measured using the 'fast' sound level meter response. |
| $L_{90,T}$ | A noise level index. The noise level exceeded for 90% of the time over the period T. L_{90} can be considered to be the 'average minimum' noise level and is often used to describe the background noise. |
| Free-Field | Far from the presence of sound reflecting objects (except the ground), usually taken to mean at least 3.5m |
| Ambient Noise Level | The totally encompassing sound in a given situation at a given time, usually composed of a sound from many sources both distant and near ($L_{Aeq,T}$). |
| Residual Noise Level | The ambient noise remaining at a given position in a given situation when specified sources are suppressed to a degree such that they do not contribute to the ambient noise level ($L_{Aeq,T}$) |
| Specific Noise Level | The equivalent continuous A-weighted sound pressure level at the assessment position produced by the specific noise source (the noise source under investigation) over a given time interval ($L_{Aeq,T}$) |
| Rating Noise Level | The specific noise level plus any adjustment for the characteristic features of the noise ($L_{Ar,Tr}$). |
